NxtGen | Secure | Scalable | Cost-Efficient

Prepared from SpeedCloud-Supreme - Brochure Aug2026

01 | EXECUTIVE READING

The brochure describes an exit path from VMware to a managed OpenShift private cloud

The August 2026 brochure positions SpeedCloud Supreme as a fully managed private cloud powered by Red Hat OpenShift. It promises a VMware-like experience with open-source economics, support for enterprise and mission-critical workloads, AI readiness, managed security and recovery, and deployment on premises or in NxtGen data centres. The document is a product overview; the customer-specific design, benchmark, service boundary, and commercial terms still need to be defined.

Brochure message	Technical interpretation	Example use
Accelerating escape from VMware	Replace a proprietary virtualization operating model while preserving familiar VM workflows and introducing container operations where useful.	Migrate a low-risk VM wave first, then modernize selected services into containers without a big-bang rewrite.
Powered by Red Hat OpenShift	Use OpenShift for orchestration, virtualization, container platform services, policy, and lifecycle automation; confirm exact edition and features.	Run VMs and containers on a common managed platform with shared identity, network, monitoring, and protection.
10x advantages and cost of license or less	Commercial and performance positioning that requires a defined baseline, workload, service level, capacity, and protection model.	Build a like-for-like three-year comparison including license, support, migration, backup, DR, staff, and exit costs.
AI inference ready	Provide an inference landing zone with OpenShift and optional GPU profiles; model, latency, throughput, and data controls determine fit.	Run CPU-friendly inference first, or select an RTX PRO 6000 or B200/B300 profile for accelerator-dependent models.
Fully managed 24/7	Provider-operated platform, security, backup, recovery, and support with an SLA and explicit responsibility boundary.	An application team consumes a managed platform while retaining application, data, and business ownership.

How to use this guide

- Treat the brochure as a set of hypotheses for a migration and proof of concept, not as a complete architecture or contract.
- Ask for the baseline behind every comparison, especially 10x performance, cost of license or less, and zero-commitment deployment.
- Separate platform capabilities from application migration, data governance, identity, compliance, and business continuity responsibilities.
- Use the checklist near the end to turn the brochure into a decision record.

02 | PLATFORM ARCHITECTURE

One managed stack can expose VMs, containers, storage, orchestration, and services

The architecture page shows VMs and containers at the workload layer, OpenShift virtualization and container platform functions in the orchestration layer, three physical servers, OpenShift Data Foundation, and managed services around the stack. This suggests a converged operating model, but capacity, failure domains, and service boundaries must be confirmed for each deployment.

Layer	Role	Technical questions
VM workloads	Preserve existing enterprise workloads and familiar VM lifecycle patterns during migration.	Which source hypervisors, guest OS versions, devices, snapshots, HA policies, and conversion methods are supported?
Containers	Provide a landing zone for APIs, workers, automation, and cloud-native services.	Which registry, ingress, operators, namespaces, quotas, secrets, storage classes, and network policies are included?
OpenShift virtualization and container platform	Orchestrate both workload patterns with a common control and lifecycle model.	Which OpenShift edition, version, subscriptions, upgrade policy, and support scope apply?
Three-server physical infrastructure	Provide the compute and failure-domain foundation for a compact cluster.	What are usable CPU, memory, storage, network, resilience, expansion, and maintenance limits?
OpenShift Data Foundation	Provide the data layer for persistent workloads and platform services.	What replication, usable capacity, encryption, rebuild, performance, backup, and recovery behavior is guaranteed?
Managed services	Operate monitoring, patching, security, backup, DR, incidents, and support around the platform.	What is included in the SLA, what is customer-owned, and how are maintenance and capacity events handled?

Example: coexistence without a big-bang migration

- Keep a packaged ERP or legacy application on VMs while moving new APIs and workers to containers.
- Use common identity, network segmentation, logging, backup, patching, and incident processes across both patterns.
- Document data paths, firewall rules, service discovery, storage access, DNS, load balancing, and rollback for each workload.

Architecture evidence to request

Request a logical and physical diagram with server roles, storage pools, control plane, tenant boundaries, failure domains, management access, backup and DR locations, network paths, and capacity headroom. A three-server diagram does not by itself prove high availability or recovery behavior.

03 | VMWARE MODERNIZATION

A familiar VM experience still requires a deliberate dependency and cutover plan

The brochure frames Supreme as a future-proof VMware replacement. The difficult part of migration is rarely copying a virtual disk alone; it is preserving identity, network policy, storage behavior, backup, monitoring, licensing, operational skills, and application dependencies while the platform changes underneath.

Migration area	What to assess	Example evidence
Inventory	VMs, OS versions, CPU and memory, storage, IPs, dependencies, owners, criticality, and maintenance windows.	Exported inventory, utilization baseline, dependency map, and migration-wave classification.
VM compatibility	Guest drivers, firmware, snapshots, templates, HA, affinity, time sync, tools, and special devices.	Conversion test, boot test, application test, restart test, and rollback runbook.
Network and identity	VLANs, firewall rules, DNS, load balancing, ingress, east-west paths, IAM, and privileged access.	Flow matrix, security approvals, access test, and cutover validation checklist.
Data protection	Backup policies, restore, replication, retention, RPO/RTO, consistency, and ransomware recovery.	Restore evidence, DR drill, application-consistency test, and sign-off.
Operations	Monitoring, patching, incident response, change, capacity, support escalation, and skills.	RACI, service catalogue, alert routing, change templates, and SLA matrix.

Example: three migration waves

- Wave 1: development, utility, and low-dependency VMs to prove conversion, networking, backup, and support.
- Wave 2: stateless application tiers after identity, load balancing, observability, and rollback validation.
- Wave 3: stateful databases and mission-critical services after restore, DR, consistency, and business sign-off.
- Retire the source only after the agreed stabilization period and rollback window have closed.

Migration success is more than VM start-up

Acceptance should cover user transactions, performance, scheduled jobs, monitoring, backup, recovery, security, cost, and operational ownership. A VM that powers on but loses its backup, identity, or application dependencies is not a successful migration.

04 | AI AND GPU READINESS

Use the right accelerator profile for the model and business target

The brochure describes AI inference readiness and shows two accelerator-oriented configurations: an RTX PRO 6000 Blackwell profile with 8 GPUs at 96 GB and a Blackwell Series profile with Red Hat OpenShift, NVIDIA AI Enterprise, 8 NVIDIA B200/B300 GPUs at 180 GB, and 200 Gbps networking using two 100 GbE switches. These are solution options, not a substitute for workload sizing.

Profile shown	Positioning in brochure	Questions to close
RTX PRO 6000 Blackwell	Multi-media performance, Red Hat OpenShift, 8 x NVIDIA RTX PRO 6000 Blackwell at 96 GB, and 200 Gbps network using 2 x 100 GbE switches.	Is the target inference, visualization, fine-tuning, or training? What precision, model size, concurrency, memory utilization, and isolation are required?
NVIDIA B200/B300	Universal AI applications, Red Hat OpenShift and NVIDIA AI Enterprise, 8 x NVIDIA B200/B300 at 180 GB, and 200 Gbps networking.	Which B200/B300 variant, software stack, licensing, topology, interconnect, scheduling, and support model are included?
CPU-first inference	A lower-complexity starting point for models that meet latency and throughput targets without GPUs.	What is the target p95/p99 latency, requests per second, accuracy, cost per inference, and scaling behavior?

Example: AI proof of concept

- Define the model, framework, precision, input size, data path, expected accuracy, and request pattern.
- Test CPU inference first if the workload is suitable; compare against the selected GPU profile using the same data and software version.
- Measure p50, p95, and p99 latency, throughput, GPU utilization, memory use, queueing, cost per thousand inferences, and failure behavior.
- Validate model packaging, container image security, registry, secrets, observability, versioning, rollback, and data retention.

AI governance remains part of the design

The platform can simplify deployment, but the customer still owns model risk, privacy, data quality, explainability, bias review, retention, human oversight, and business approval. Include those controls in the pilot and production runbook.

05 | PERFORMANCE, NETWORKING, AND COST

The brochure's headline advantages need a like-for-like baseline

The brochure states 10x better performance and value versus traditional private cloud, cloud at the cost of existing licenses or less, and 200 Gbps networking in the AI configurations. These are compelling positioning statements, but the comparison is only meaningful when the baseline includes equivalent workload, resilience, protection, support, and capacity growth.

Claim or design signal	What to measure	Example validation
10x better performance and value	Define performance metric, workload, baseline private cloud, concurrency, software, protection overhead, and price scope.	Compare transactions per second, job completion time, p95/p99 latency, and three-year cost under the same service level.
200 Gbps network	Path, host or VM scope, packet size, protocol, loss, latency, jitter, topology, and shared capacity.	Measure application, replication, backup, and GPU data paths through actual switches, controls, and encryption.
Cost of license or less	Subscription, support, migration, backup, DR, security, connectivity, staff, growth, egress, and exit costs.	Build a three-year TCO with current, peak, and growth scenarios and written assumptions.
Superior performance	CPU, memory, storage, network, application response, availability, and recovery together.	Run a representative VM, database, API, backup, and AI workload with agreed acceptance thresholds.

Example: network and GPU data-movement test

- Measure host-to-host, VM-to-VM, and GPU-to-GPU or GPU-to-storage paths separately.
- Record throughput, latency, packet loss, CPU overhead, GPU utilization, storage impact, and application or training time.
- Repeat through firewalls, encryption, scheduling, tenant isolation, and monitoring if those components are in production.

TCO checklist

- Include existing VMware or virtualization licensing, OpenShift and AI software, hardware or service fees, support, backup, DR, security, connectivity, and migration.
- Include resilience and recovery copies; a smaller footprint is not a saving if protection was removed.
- State the meaning of zero commitment, conversion, trial expiry, data export, and exit assistance in the commercial model.

06 | SECURITY, MANAGED SERVICES, AND RECOVERY

Fully managed means the operating boundary must be explicit

The brochure lists advanced security, fully managed 24/7, managed server protection, and cloud recovery. Turn those labels into a service catalogue, RACI, access model, incident process, backup policy, DR plan, and SLA with measurable outcomes.

Service area	Provider activity to confirm	Customer input or responsibility
Platform operations	Cluster health, capacity, patching, upgrades, monitoring, incident response, maintenance, and support.	Business priority, change approval, application validation, access governance, and risk acceptance.
Security	Hardening, vulnerability management, endpoint or server protection, logging, alerting, and incident coordination.	Identity policy, application security, data classification, remediation ownership, and notification contacts.
Backup	Policy configuration, backup monitoring, immutability, retention, restore support, and reporting.	Retention, application consistency, recovery priority, restore validation, and business sign-off.
Cloud recovery	DR location, replication, runbook, failover, failback, drills, and RPO/RTO reporting.	Application order, DNS or routing change, recovery declaration, test participation, and acceptance.
SLA and support	Availability, response, resolution, maintenance, capacity, service credits, escalation, and reporting.	Named owners, approvals, dependencies, escalation path, and agreed business impact thresholds.

Security and sovereignty questions

- Where are primary data, backups, replicas, logs, support exports, and temporary files stored and processed?
- Which provider roles can access infrastructure, VMs, containers, logs, or customer data, and from where?
- What encryption, key ownership, MFA, RBAC, session logging, vulnerability SLAs, and incident notification apply?
- Which regulatory or sovereign control scope is evidenced for the selected facility, service, workload, and support model?

Example: recovery acceptance test

Restore a representative VM, database, container service, and AI metadata or model artifact. Execute a planned failover, record elapsed time and data loss, validate the application, then document failback, ownership, and audit evidence. Acceptance should use business RPO and RTO, not only a backup-success percentage.

07 | DEPLOYMENT AND 90-DAY ZERO-COMMITMENT PLAN

Make the trial a controlled technical decision

The brochure promises 90 days of zero-commitment deployment. A useful trial has a defined scope, data handling rules, success thresholds, support model, checkpoints, rollback, and end-of-trial decision. Without those elements, a trial can demonstrate a demo path without proving production readiness.

Stage	Technical activity	Exit evidence
Assess	Inventory VMs, containers, applications, data, dependencies, performance, RPO/RTO, AI model, and security requirements.	Signed scope, architecture, sizing, migration waves, risks, and acceptance plan.
Build	Deploy or allocate OpenShift, VM and container services, storage, network, identity, monitoring, security, backup, and DR.	Access, smoke, capacity, protection, security, and operational handover tests.
Migrate and test	Move selected workloads; validate functionality, performance, security, backup, restore, recovery, and AI inference or GPU behavior.	Business sign-off, measured results, rollback decision, known issues, and production runbook.
Decide	Compare results with thresholds, cost assumptions, support commitments, and migration effort.	Proceed, revise, or stop decision with commercial and technical actions.

Trial checklist

- Define included workloads, locations, users, data classes, OpenShift features, GPU access, support hours, and service levels.
- Agree thresholds for application response, compute, storage, network, AI inference, availability, backup, restore, DR, security, cost, and operator effort.
- Set trial expiry, data deletion, export, rollback, conversion, and exit-assistance terms before loading sensitive data.
- Schedule checkpoints after platform readiness, first migration, workload testing, recovery drill, and final review.

Example trial scope

Use one low-risk VM, one application or database tier, one containerized API, one backup and restore path, and one AI inference workload. Add a GPU profile only when the model and acceptance target require it. This demonstrates the brochure's core value without committing the full estate before evidence exists.

08 | TECHNICAL QUALIFICATION CHECKLIST

Questions to answer before production commitment

Use these questions with infrastructure, security, application, procurement, operations, and risk teams. The answers should become part of the proposal, statement of work, service description, test plan, and decision record.

Decision area	Questions to close
Source platform	Which VMware versions, guest OS, tools, storage, network, snapshots, devices, and dependencies are in scope? What is the migration and rollback method?
OpenShift	Which edition and version are included? Are OpenShift virtualization, container platform, registry, ingress, operators, namespaces, and upgrades covered?
Cluster and storage	What are the three-node CPU, memory, storage, network, failure-domain, usable-capacity, rebuild, expansion, and maintenance limits?
AI and GPU	Is the workload CPU or GPU suitable? Which RTX PRO 6000 or B200/B300 profile, AI software, licenses, topology, and scheduling are included?
Performance	What baseline supports 10x, cost of license or less, 200 Gbps, and any application performance promise? Are resources dedicated or shared?
Security and sovereignty	Where is the service hosted and operated? What encryption, IAM, logging, vulnerability, incident, audit, and regulatory evidence applies?
Managed service	Who owns platform, OS, application, data, identity, security, backup, DR, incident response, maintenance, and change approval?
Commercials	What does zero commitment mean? What are trial conversion, support, growth, egress, migration, export, exit, service-credit, and renewal terms?

Minimum evidence pack

- Logical and physical architecture, capacity and failure-domain design, network and data-flow diagrams.
- Workload inventory, migration plan, test plan, rollback runbook, backup and DR runbooks, and RACI.
- Benchmark configuration, baseline, raw results, application acceptance metrics, and three-year TCO.
- Security control matrix, regulatory scope, access model, incident process, and current service commitments.

Decision rule

Proceed when the proposed design meets workload thresholds, the service boundary is explicit, recovery objectives are proven, security and regulatory evidence is in scope, and the commercial model remains valid under growth and protection requirements.

09 | CONCLUSION

The brochure's value is the combination of migration, managed operations, and AI-ready infrastructure

The August 2026 brochure presents SpeedCloud Supreme as a VMware alternative with a managed OpenShift foundation, VM and container coexistence, private-cloud economics, recovery and security services, and optional high-bandwidth GPU infrastructure. The most defensible next step is a scoped trial that proves the customer workload rather than relying on headline comparisons.

Theme	Technical takeaway	Proof required
VMware escape	A platform migration plus operating-model change, not only a hypervisor replacement.	Inventory, dependency map, conversion, performance, backup, DR, rollback, and sign-off.
OpenShift platform	A common landing zone for VMs, containers, orchestration, automation, and policy.	Edition, version, features, capacity, lifecycle, licensing, and support boundaries.
AI readiness	CPU inference and GPU profiles can support different model and performance needs.	Model benchmark, latency, throughput, accuracy, GPU topology, data governance, and cost.
Private-cloud value	Managed security, backup, recovery, and support can reduce operational load.	RACI, SLA, RPO/RTO, restore and failover evidence, access controls, and incident process.
10x and cost claims	Potentially attractive comparison, but only after baseline and like-for-like scope are fixed.	Repeatable tests, workload metrics, three-year TCO, protection, growth, and exit assumptions.

Bottom line

Use this brochure to start a VMware modernization and AI infrastructure conversation. Approve production only after the proposed OpenShift architecture, migration method, AI or GPU profile, managed-service boundary, security scope, recovery outcomes, and commercial assumptions have been tested and documented.

Source note

Product positioning, technology names, GPU profiles, networking figures, and commercial language in this guide are based on the supplied SpeedCloud-Supreme - Brochure Aug2026. Claims such as 10x performance and value, cost of license or less, zero-commitment deployment, and AI readiness should be confirmed in the customer-specific proposal, test plan, service description, and contract.
